

Equal but Inequitable: Who Benefits from Gender-Neutral Tenure Clock Stopping Policies
Antecol, Bedard, and Stearns
AER

Replication Notes:

The Stata .do file aer_regressions.do contains the code to replicate all the tables and figures. This file calls in several Stata datasets, which are described below.

To maintain the anonymity of the individuals in the data, we have removed the names of the individuals and the universities, as well as the year the individual was hired at the policy university. Most regressions include fixed effects for the policy university (pol_u) and the year the associated job was started (pol_job_start). The numerical values for these variables are randomized and have no ordinal properties. Figure 2 and Table 3 use more detailed information about the timing of hiring. As such, there are separate datasets for these Figures and Tables that contain the relevant information. The values of the policy university and policy job start variables are re-randomized and are different across samples. The fertility subsample for Table 7 does not include the policy university or year of job start to protect the anonymity of the sample of respondents. The dataset for Table 9 is a panel of university characteristics in each year (one observation per university-year) and does not contain data on the individuals in the main sample.

The main dataset (aer_primarysample) is used to create Tables 2, 4, 5, 6, and 8, and includes data on all individuals hired between 1980 and 2005 whose first job was an assistant professor at one of the universities in our sample, who started within two years of receiving a PhD and who published at least two papers within eight years of receiving the PhD. The dataset aer_expandedsample is used for one of the columns of Table 4 and includes individuals with less than two publications or who started their first job more than two years after completing their PhD.

Because many of the coefficients of interest reported in the tables are linear combinations of the coefficients estimated directly in the regressions, the main .do file calls in several other .do files (tableX_tests.do) to produce the coefficients in the reported tables. These files use the “lincom” command and are called in simply to keep the main file more readable.

The independent variables of interest are indicators for whether or not there is a gender-neutral or female-only clock stopping policy in place in the year the job starts:

gncs: a gender-neutral policy is in place

focs: a female-only policy is in place

gncs0: a gender-neutral policy is in place and 0-3 years since policy adoption

focs0: a female-only policy is in place and 0-3 years since policy adoption

f_gncs, f_focs, f_gncs0, f_focs0: policy variables interacted with female

The main outcomes are:

tenure_policy_school: indicator for getting tenure at the policy university

tenure_anywhere: indicator for getting tenure at any university

time_policy: number of years spent at the policy university as an assistant professor
leave_early: indicator for leaving the policy university before the fifth year
late_move: indicator for being an assistant professor at the policy university more than the modal number of years for men in that university in years when no gender-neutral policy is in place
time_to_tenure: number of years between starting the first job and getting tenure at any university; defined only for individuals who get tenure anywhere
jobs_to_associate: number of tenure-track jobs held before getting tenure; defined only for individuals who get tenure anywhere
down: indicator for moving to a lower-tier university; defined only for individuals who do not get tenure at the policy university
up: indicator for moving to a higher-tier university; defined only for individuals who do not get tenure at the policy university
top_pubsX: cumulative number of peer-reviewed publications in top-5 journals by year X (3, 5, 7, and 9) since PhD completion
PUBSX: cumulative number of non-top-5 peer-reviewed publications by year X (3, 5, 7, and 9) since PhD completion

Main control variables used include:

female: indicator for female
pol_u: policy university identifier (values are randomized)
pol_job_start: identifier for year the job at the policy university started (values are randomized)
phd_rank: 1-5 categorical variable of PhD program tier based on placements into the top-50 departments in our sample
phd_rank_miss: indicator for missing PhD information
post_doc: indicator for doing a post-doc before the first tenure-track position

The following control variables are from IPEDS and are measured at the university-year level:

ug_students: number of undergraduate students at the university, in thousands
grad_students: number of graduate students at the university, in thousands
faculty: number of faculty at the university (all disciplines), in hundreds
full_av_salary: average salary of full professors at the university, in thousands
assist_av_salary: average salary of assistant professors at the university, in thousands,
revenue: annual revenue of the university, in 10,000,000s
female_ratio: fraction of the faculty at the university who are female
full_ratio: fraction of the faculty at the university who are full professors

Additional control variables included in specifications in Table 4:

mean_ca7: mean number of coauthors on peer-reviewed papers published in top-5 journals within 7 years of PhD completion
max_csstops: number of children born within five years of PhD completion
max_csstops_miss: indicator for missing fertility information
RANK: equal to 1 for top-10 departments and 2 for all other departments

The remaining tables and figures call in additional datasets:

Table 3 uses the dataset aer_eventstudysample, which also includes:

pre1: indicator for 1-6 years before the first clock stopping policy is implemented

pre2: indicator for 7-12 years before the first clock stopping policy is implemented

pre3: indicator for 13-18 years before the first clock stopping policy is implemented

f_pre1, f_pre2, and f_pre3: pre-policy indicators interacted with female

Table 7 uses the dataset aer_fertilitysample, which includes the outcomes:

any_birth: indicator for having at least one child within 5 years of PhD completion

all_birth: number of children by 5 years after PhD completion

havekids: indicator for ever having at least one child

numkids: number of children ever born

Table 9 uses the dataset aer_predictsample and contains (in addition to the IPEDS variables):

year_80s: indicator for years 1980-1989

year_90_05: indicator for years 1990-2005

gnscs80, focs80: indicator for clock stopping policies implemented by 1984

gnscs85, focs85: indicator for clock stopping policies implemented by 1989

gnscs05, focs05: indicator for clock stopping policies implemented by 2005

YEAR: equal to 1980 for years 1980-1984; equal to 1985 for years 1985-1989

Figure 1 uses data from the 2000 Census and 2010 ACS. The data file aer_acs.dta contains information on individuals in the 1970 birth cohort with advanced degrees, and the figure is created through the file called aer_figure1.do.

Finally, the data for Figure 2 is provided in aer_figure2_sample. The data is collapsed to the year individuals started the job at the policy university and contains:

policy_job_start: year job at the policy university started

av_numberX: average number of assistant professors hired

av_tenureX: average tenure rate

av_topX: average number of top-5 peer-reviewed publications within 7 years of PhD completion

av_pubsX: average number of non-top-5 peer-reviewed publications within 7 years of PhD completion

X=0 indicates the average for men and X=1 indicates the average for women. All averages are computed using a 7 year moving average for smoothness.
